In classical mechanics, torque is represented by the 3D vector cross product of the position vector **r** with the force **f**, that is **r** x **f**. The cross product of Octonion position **r** and Octonion force **f** is represented by a subset of product terms from the full up Octonion product **r** * **f**. These product terms are those where the component indices of both **r** and **f** are unequal and not scalar. In any of the 16 possible Octonion Algebra representations [1][2], each of these product types anti-commutes. They may therefore be separated from the other product terms in the full Octonion product with the following expression for torque

T = ½ [**r** * **f** – **f** * **r**]

Torque is a physical observable, and as such, its Octonion representation must be an Octonion Algebraic Invariant [1][3]. The expression above for torque will separate via the Octonion Variance Sieve [1][4] into invariant and variant product term sets. As such, all variant product term sets must be equated to zero independent of whether or not the system has non-zero torque. For a closed and stable physical system, even the invariant product term set for torque must be equated to zero to conserve angular momentum.

The Octonion expression for force is [1][5]

Invariant { **F***j } = **f**

Here **F** is the expression for the (vector component only) field components derived from the 8-potential functions as a single application of the Ensemble Derivative [1][6] on the 8-potentials and **j** is the 8-current. The 8-current form which includes the 8 dimensional equivalent of the D'Alembertian and 8-gradient of the Analogous Lorentz Condition, was shown in the references to be a straight up full algebraic invariant. As such, it may be represented in any algebraic variance sieve as simply **j** rather than a history of product orderings. The field representation has a mix of variant (like the magnetic field) and invariant (like the electric field). Its full product history must be and was included in the variance sieve of the general force.

Similarly, the proper sieve of the torque must include the full product history of all constituents where octonion multiplications may have resulted in intermediate variant terms. Thus, we must use the full product **F***j in the torque variance sieve and not just its invariant product terms. The torque expression is thus

T = ½ [**r** * [**F** *j] – [**F** * **j**] * **r**]

Running this expression through the Octonion Variance Sieve gives the following component results for rectilinear result basis [n]
